Parallel Processing

Winter Term 2024/25

1 Repetition / Foundations

Contents

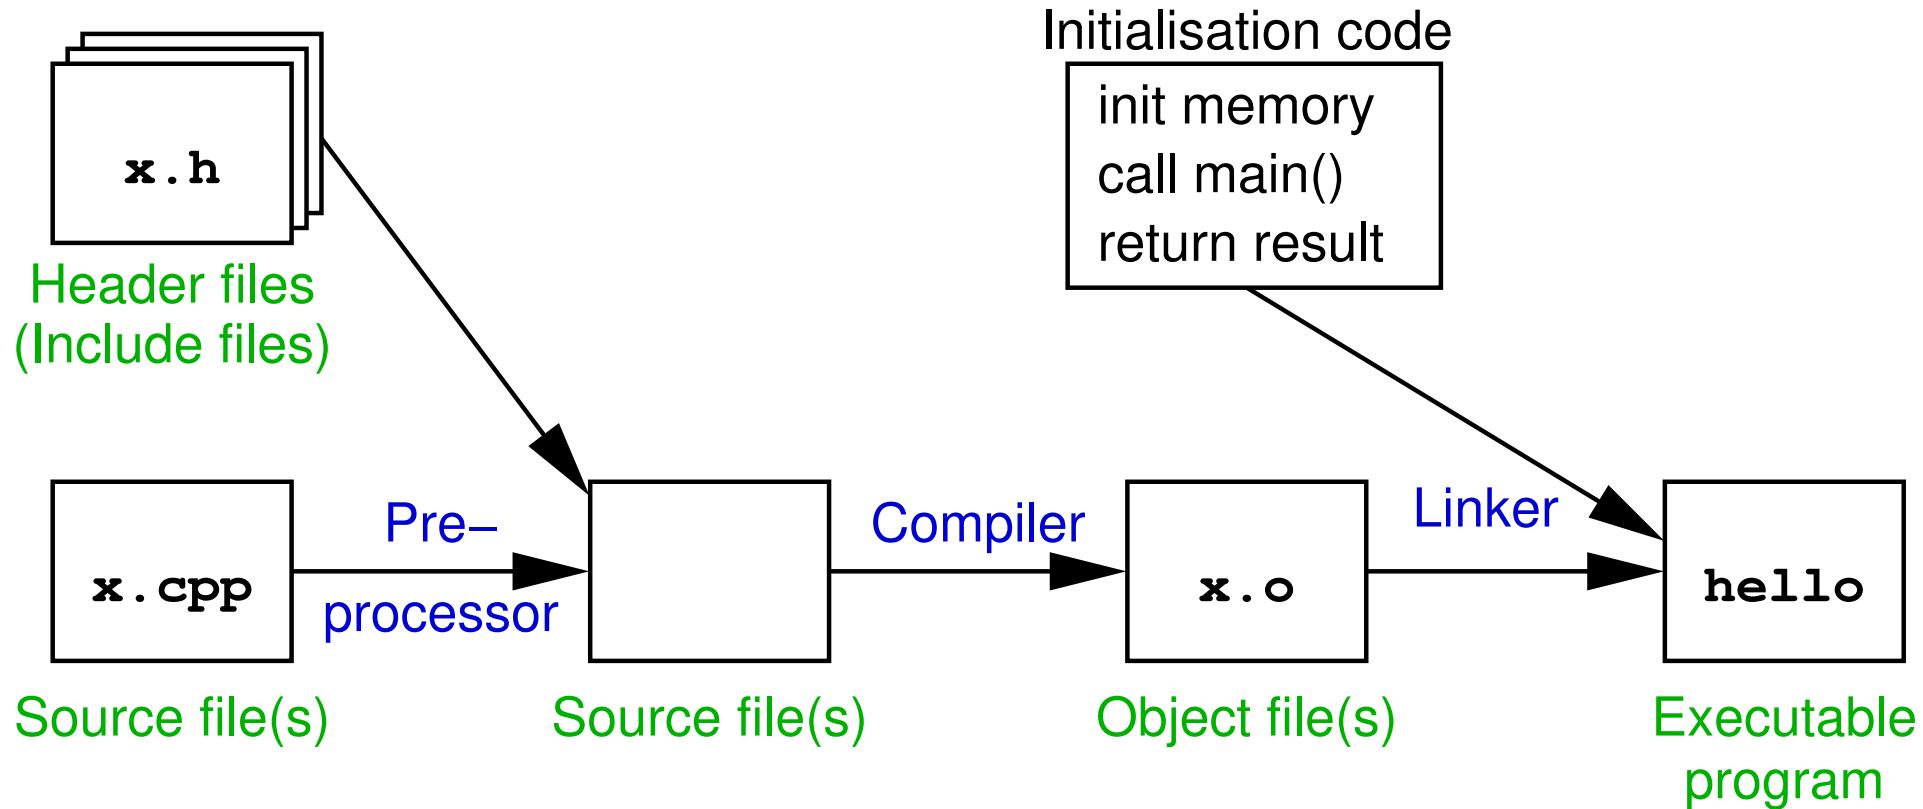

- C/C++ for Java programmers
- Threads and synchronisation
- C++ threads

1.1 C/C++ for Java Programmers

1.1.1 Fundamentals of C++

- Commonalities between C++ and Java:
 - ↳ imperative programming language
 - ↳ syntax is mostly identical
- Differences between C++ and Java:
 - ↳ C++ is not purely object oriented
 - ↳ C++ programs are translated directly to machine code (no virtual machine)
- Usual file structure of C++ programs:
 - ↳ header files (*.h) contain declarations
 - ↳ types, classes, constants, ...
 - ↳ source files (*.cpp) contain implementations
 - ↳ methods, functions, global variables

Compilation of C++ programs

- Preprocessor: embedding of files, expansion of macros
- Linker: binds together object files and libraries

1.1.1 Fundamentals of C++ ...

Compilation of C++ programs ...

- Invocation of the GNU C++ compiler:
 - `g++ -Wall -o <output-file> <source-files>`
 - executes preprocessor, compiler and linker
 - `-Wall`: report all warnings
 - `-o <output-file>`: name of the executable file
- Additional options:
 - `-g`: enable source code debugging
 - `-O`: enable code optimization
 - `-l<library>`: link the given library
 - `-c`: do not execute the linker
 - later: `g++ -o <output-file> <object-files>`

1.1.1 Fundamentals of C++ ...

An example: *Hello World!* (01/hello.cpp)

```
#include <iostream>      // Preprocessor directive: inserts contents of file
                           // 'iostream' (e.g., declaration of cout)

using namespace std; // Import all names from namespace 'std'

void sayHello() {           // Function definition
    cout << "Hello World!\n"; // Print a text to console
}

int main() {                // Main program
    sayHello();
    return 0;                 // Convention for return value: 0 = OK, 1,...,255: error
}
```

- Compilation: g++ -Wall -o hello hello.cpp
- Start: ./hello

1.1.1 Fundamentals of C++ ...

Syntax

- Identical to Java are among others:
 - declaration of variables and parameters
 - method calls
 - control statements (if, while, for, case, return, ...)
 - simple data types (short, int, double, char, void, ...)
 - deviations: bool instead of boolean; char has a size of 1 Byte
 - virtually all operators (+, *, %, <<, ==, ?:, ...)
- Very similar to Java are:
 - arrays
 - class declarations

1.1.2 Data types in C++

Arrays

- Declaration of arrays

- only with fixed size, e.g.:

```
int ary1[10]; // int array with 10 elements
```

```
double ary2[100][200]; // 100 * 200 array
```

```
int ary3[] = { 1, 2 }; // int array with 2 elements
```

- for parameters: size can be omitted for **first** dimension

```
int funct(int ary1[], double ary2[] [200]) { ... }
```

- Arrays can also be realized via pointers (see later)

- then also dynamic allocation is possible

- Access to array elements

- like in Java, e.g.: `a[i][j] = b[i] * c[i+1][j];`

- but: **no** checking of array bounds!!!

1.1.2 Data types in C++ ...

Classes and objects

- Declaration of classes (typically in .h file):

```
class Example {  
    private:           // private attributes/methods  
        int attr1;          // attribute  
        void pmeth(double d); // method  
    public:           // public attributes/methods  
        Example();          // default constructor  
        Example(int i);      // constructor  
        Example(Example &from); // copy constructor  
        ~Example();         // destructor  
        int meth();         // method  
        int attr2;          // attribute  
        static int sattr;   // class attribute  
};
```

1.1.2 Data types in C++ ...

Classes and objects ...

- Definition of class attributes and methods (*.cpp file):

```
int Example::sattr = 123; // class attribute

Example::Example(int i) { // constructor
    this->attr1 = i;
}

int Example::meth() {      // method
    return attr1;
}
```

- specification of class name with attributes and methods
 - separator :: instead of .
 - this is a pointer (☞ 1.1.3), thus this->attr1
 - alternatively, method bodies can also be specified in the class definition itself

1.1.2 Data types in C++ ...

Classes and objects ...

- Declaration of objects:

```
{  
    Example ex1;          // initialisation using default constructor  
    Example ex2(10);     // constructor with argument  
    ...  
} // now the destructor for ex1, ex2 is called
```

- Access to attributes, invocation of methods

```
ex1.attr2 = ex2.meth();  
j = Example::sattr;      // class attribute
```

- Assignment / copying of objects

```
ex1 = ex2;              // object is copied!  
Example ex3(ex2);       // initialisation using copy constructor
```

1.1.2 Data types in C++ ...

Templates

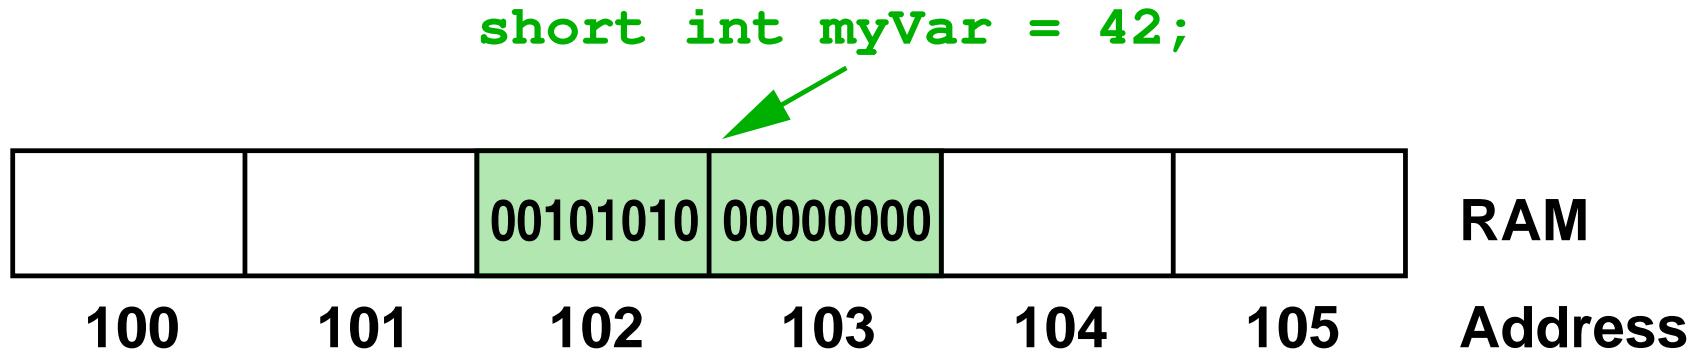

- Somehow similar to generics in Java
 - i.e., classes (and methods) may have type parameters
 - however, templates are more powerful (and complex) than generics
- Main goal: allow to implement generic classes / data structures, e.g., lists
- Usage of templates:

```
std::list<int> intlist;           // List of integers
intlist.push_back(42);             // Add at the end of the list
int i = intlist.front();           // First element
std::list<double> dbllist;         // List of doubles
dbllist.push_back(3.1415);
```

1.1.3 Pointers

Variables in memory

- Reminder: variables are stored in main memory

- a variable gives a name and a type to a memory block
 - here: `myVar` occupies 2 bytes (`short int`) starting with address 102
- A **pointer** is a memory address, together with a type
 - the type specifies, how the memory block is interpreted

1.1.3 Pointers ...

Declaration and use of pointers

- Example:

```
int myAge = 25; // an int variable
```

- The **address operator** & determines the address of a variable
- The access to *pAge is called **dereferencing** pAge
- Pointers (nearly) always have a type
 - e.g. int *, Example *, char **, ...

1.1.3 Pointers ...

Declaration and use of pointers

- Example:

```
int myAge = 25;           // an int variable  
int *pAge;                // a pointer to int values
```

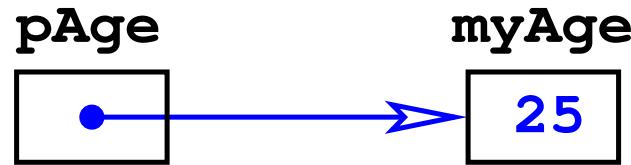

- The **address operator** & determines the address of a variable
- The access to `*pAge` is called **dereferencing** `pAge`
- Pointers (nearly) always have a type
 - e.g. `int *`, `Example *`, `char **`, ...

1.1.3 Pointers ...

Declaration and use of pointers

- Example:

```
int myAge = 25;           // an int variable
int *pAge;                // a pointer to int values
pAge = &myAge;             // pAge now points to myAge
```

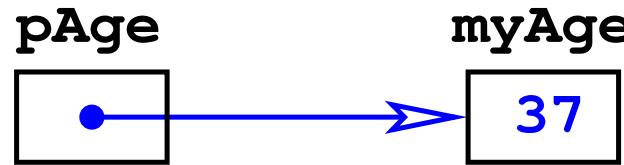

- The **address operator** & determines the address of a variable
- The access to *pAge is called **dereferencing** pAge
- Pointers (nearly) always have a type
 - e.g. int *, Example *, char **, ...

1.1.3 Pointers ...

Declaration and use of pointers

- Example:

```
int myAge = 25;           // an int variable
int *pAge;                // a pointer to int values
pAge = &myAge;              // pAge now points to myAge
*pAge = 37;                // myAge now has the value 37
```

- The **address operator** & determines the address of a variable
- The access to `*pAge` is called **dereferencing** `pAge`
- Pointers (nearly) always have a type
 - e.g. `int *`, Example `*`, `char **`, ...

“Creativity is Intelligence having Fun”

- Albert Einstein

1.1.3 Pointers ...

Passing parameters *by reference*

- Pointers allow to pass parameters *by reference*
- Instead of a value, a **pointer** to the values is passed:

```
void byReference(Example *e, int *result) {  
    *result = e->attr2;  
}  
  
int main() {  
    Example obj(15);           // obj is more efficiently  
    int res;                  // passed by reference  
    byReference(&obj, &res);   // res is a result parameter  
    ...  
}
```

- short notation: `e->attr2` means `(*e).attr2`

1.1.3 Pointers ...

void pointers and type conversion

- C++ also allows the use of generic pointers
 - just a memory address without type information
 - declared type is `void *` (pointer to `void`)
- Dereferencing only possible after a type conversion
 - caution: no type safety / type check!
- Often used for generic parameters of functions:

```
void bsp(int type, void *arg) {  
    if (type == 1) {  
        double d = *(double *)arg; // arg must first be converted  
                                // to double *  
    } else {  
        int i = *(int *)arg;      // int argument
```

1.1.3 Pointers ...

Arrays and pointers

- C++ does not distinguish between one-dimensional arrays and pointers (with the exception of the declaration)
- Consequences:
 - array variables can be used like (constant) pointers
 - pointer variables can be indexed

```
int a[3] = { 1, 2, 3 };  
int b = *a;           // equivalent to: b = a[0]  
int c = *(a+1);     // equivalent to: c = a[1]  
int *p = a;          // equivalent to: int *p = &a[0]  
int d = p[2];        // d = a[2]
```

1.1.3 Pointers ...

Arrays and pointers ...

→ Consequences ...:

→ arrays as parameters are always passed *by reference!*

```
void swap(int a[], int i, int j) {  
    int h = a[i]; // swap a[i] and a[j]  
    a[i] = a[j];  
    a[j] = h;  
}  
  
int main() {  
    int ary[] = { 1, 2, 3, 4 };  
    swap(ary, 1, 3);  
    // now: ary[1] = 4, ary[3] = 2;  
}
```

1.1.3 Pointers ...

Dynamic memory allocation

- Allocation of objects and arrays like in Java

```
Example *p = new Example(10);  
int *a = new int[10];           // a is not initialised!  
int *b = new int[10]();         // b is initialised (with 0)
```

- allocation of multi-dimensional arrays does not work in this way
- Important: C++ does not have a garbage collection
 - thus explicit deallocation is necessary:

```
delete p;    // single object  
delete [] a; // array
```

- caution: do not deallocate memory multiple times!

1.1.3 Pointers ...

Function pointers

- Pointers can also point to functions:

```
void myFunct(int arg) { ... }  
void test1() {  
    void (*ptr)(int) = myFunct; // function pointer + init.  
    (*ptr)(10); // function call via pointer
```

- Thus, functions can, e.g., be passed as parameters to other functions:

```
void callIt(void (*f)(int)) {  
    (*f)(123); // calling the passed function  
}  
void test2() {  
    callIt(myFunct); // function as reference parameter
```

1.1.4 Strings and Output

- Like Java, C++ has a string class (`string`)
 - sometimes also the type `char *` is used
- For console output, the objects `cout` and `cerr` are used
- Both exist in the name space (packet) `std`
 - for using them without name prefix:
`using namespace std; // corresponds to 'import std.*;' in Java`
- Example for an output:
`double x = 3.14;
cout << "Pi ist approximately " << x << "\n";`
- Special formatting functions for the output of numbers, e.g.:
`cout << setw(8) << fixed << setprecision(4) << x << "\n";`
 - output with a field length of 8 and exactly 4 decimal places

1.1.5 Further specifics of C++

→ Global variables

- are declared outside any function or method
 - live during the complete program execution
 - are accessible by all functions
- Global variables and functions can be used only **after** the declaration
- thus, for functions we have **function prototypes**

```
int funcB(int n);           // function prototype
int funcA() {               // function definition
    return funcB(10);
}
int funcB(int n) {          // function definition
    return n * n;
}
```

1.1.5 Further specifics of C++ ...

- Keyword `static` used with the declaration of global variables or functions

```
static int number;
```

```
static void output(char *str) { ... }
```

- causes the variable/function to be visible only in the local source file

- Keyword `const` used with the declaration of variables or parameters

```
const double PI = 3.14159265;
```

```
void print(const char *str) { ... }
```

- causes the variables to be read-only
- roughly corresponds to `final` in Java
- (note: this description is extremely simplified!)

1.1.5 Further specifics of C++ ...

- ▶ Passing command line arguments:

```
int main(int argc, char **argv) {  
    if (argc > 1)  
        cout << "Argument 1: " << argv[1] << "\n";  
}
```

Example invocation: bslab1% ./myprog -p arg2
 Argument 1: -p

- ▶ argc is the number of arguments (incl. program name)
- ▶ argv is an array (of length argc) of strings (char *)
- ▶ in the example:
 argv[0] = "./myprog"
 argv[1] = "-p"
 argv[2] = "arg2"
- ▶ important: check the index against argc

1.1.6 C/C++ Libraries

Overview

- There are several (standard) libraries for C/C++, which always come with one or more header files, e.g.:

Header file	Library (g++ option)	Description	contains, e.g.
iostream		input/output	cout, cerr
string		C++ strings	string
stdlib.h		standard funct.	exit()
sys/time.h		time functions	gettimeofday()
math.h	-lm	math functions	sin(), cos(), fabs()
pthread.h	-pthread	threads	pthread_create()
mpi.h	-lmpich	MPI	MPI_Init()

1.1.7 The C Preprocessor

Functions of the preprocessor:

- Embedding of header file

```
#include <stdio.h> // searches only in system directories  
#include "myhdr.h" // also searches in current directory
```

- Macro expansion

```
#define BUFSIZE 100           // Constant  
#define VERYBAD i + 1;        // Extremely bad style !  
#define GOOD (BUFSIZE+1)      // Parenthesis are important!  
  
...  
int i = BUFSIZE;             // becomes int i = 100;  
int a = 2*VERYBAD;           // becomes int a = 2*i + 1;  
int b = 2*GOOD;              // becomes int a = 2*(100+1);
```

1.1.7 The C Preprocessor ...

Functions of the preprocessor: ...

- Conditional compilation (e.g., for debugging output)

```
int main() {  
    #ifdef DEBUG  
        cout << "Program has started\n";  
    #endif  
    ...  
}
```

- output statement normally will not be compiled
- to activate it:
 - either `#define DEBUG` at the beginning of the program
 - or compile with `g++ -DDEBUG ...`

1.2 Threads and Synchronization

Threads

- Activities within processes, concurrent to others
- Private resources:
 - CPU registers, including PC and stack pointer
 - local variables
- All other resources (esp. memory) are shared
- Threads are time-multiplexed to available CPU cores by the OS

1.2 Threads and Synchronization ...

Synchronization

- Ensuring conditions on the possible sequences of events in threads
 - mutual exclusion
 - temporal order of actions in different threads
- Tools:
 - shared variables
 - semaphores / mutexes
 - monitors / condition variables
 - barriers

1.2 Threads and Synchronization ...

Synchronization using shared variables

- Example: waiting for a result

Thread 1

```
// compute and  
// store result  
ready = true;  
...
```

Thread 2

```
while (!ready); // wait  
// read / process the result  
...
```

- Extension: atomic *read-modify-write* operations of the CPU
 - e.g., *test-and-set*, *fetch-and-add*
- Potential drawback: *busy waiting*
 - but: in high performance computing we often have exactly one thread per CPU ⇒ performance advantage, since no system call

1.2 Threads and Synchronization ...

Semaphores

- Components: counter, queue of blocked threads
- **Atomic** operations:
 - P() (also acquire, wait or down)
 - decrements the counter by 1
 - if counter < 0: block the thread
 - V() (also release, signal or up)
 - increments counter by 1
 - if counter ≤ 0 : wake up one blocked thread
- **Binary semaphore**
 - can only assume the positive values 0 and 1
 - usually for mutual exclusion

1.2 Threads and Synchronization ...

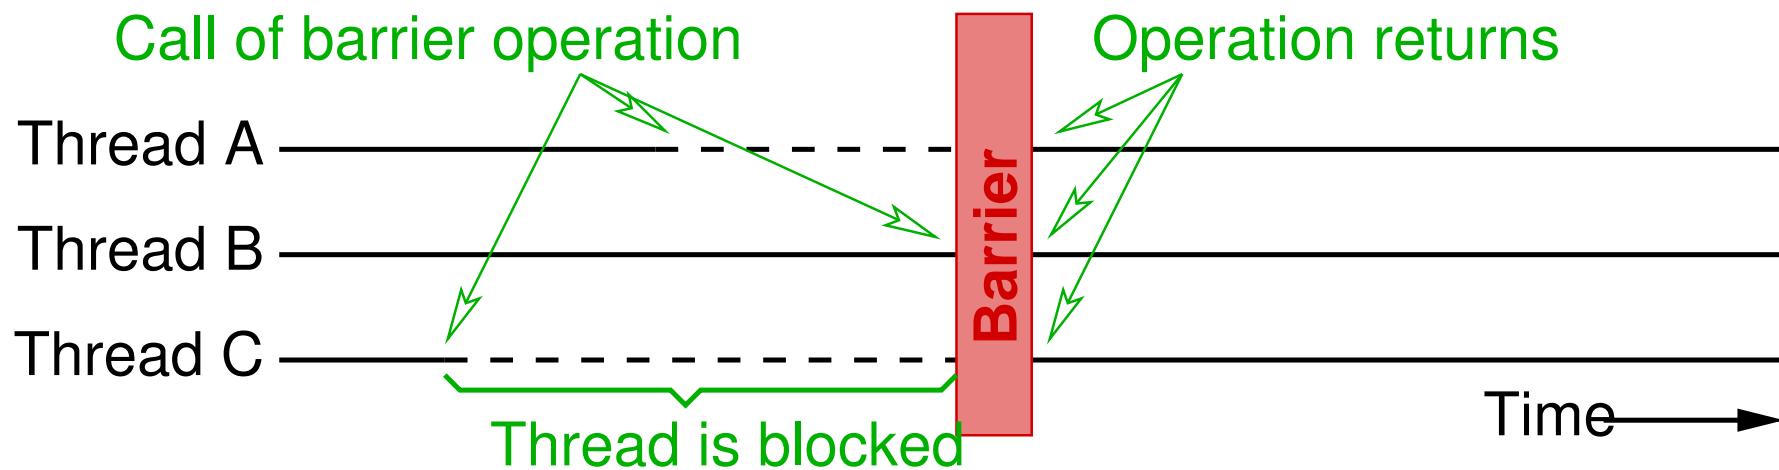

Monitors

- Module with data, procedures and initialization code
 - access to data only via the monitor procedures
 - (roughly corresponds to a class)
- All procedures are under mutual exclusion
- Further synchronization via **condition variables**
 - two operations:
 - `wait()`: blocks the calling thread
 - `signal()`: wakes up some blocked threads
 - variants: wake up only one thread / wake up all thread
 - no “memory”: `signal()` only wakes a thread, if it already has called `wait()` before

1.2 Threads and Synchronization ...

Barrier

- Synchronization of groups of processes or threads, respectively
- Semantics:
 - thread which reaches the barrier is blocked, until all other threads have reached the barrier, too

- Used to structure concurrent applications into synchronous phases

1.2 Threads and Synchronization ...

Synchronization errors

- Insufficient synchronization: *race conditions*
 - result of the calculation is different (or wrong), depending on temporal interleaving of the threads
 - important: do not assume FIFO semantics of the queues in synchronization constructs!
- Deadlocks
 - a group of threads waits for conditions, which can only be fulfilled by the other threads in this group
- Starvation (unfairness)
 - a thread waiting for a condition can never execute, although the condition is fulfilled regularly

1.2 Threads and Synchronization ...

Example for *race conditions*

- Task: synchronize two threads, such that they print something alternately
- **Wrong** solution with semaphores:

```
Semaphore s1 = 1;  
Semaphore s2 = 0;
```

Thread 1

```
while (true) {  
    P(s1);  
    print("1");  
    V(s2);  
    V(s1);  
}
```

Thread 2

```
while (true) {  
    P(s2);  
    P(s1);  
    print("2");  
    V(s1);  
}
```

1.3 C++ Threads

- Part of the C++ language standard since 2011 (C++-11)
 - implemented by the compiler and the C++ libraries
 - independent of operating system
- Programming model:
 - at program start: exactly one (master) thread
 - master thread creates other threads
and should wait for them to finish
 - process terminates when master thread terminates
 - when other threads are still running, an error is raised

1.3 C++ Threads ...

Creating threads

- Class `std::thread`
 - represents a running thread
- Creation of a new thread (both C++-object and OS thread):

```
std::thread myThread(function, args ...);
```

- with this declaration, the C++ object (and the OS thread) is automatically destroyed when the current scope is left
- *function*: the function that should be executed by the thread
- *args* ...: any number of parameters, which will be passed to *function*
- *function* cannot have a return value
 - use result parameters instead

1.3 C++ Threads ...

Methods of class `thread` (incomplete)

- ▶ `void join()`
 - ▶ waits until the thread execution has completed
 - ▶ after this method returns, the thread can be destroyed safely
- ▶ `void detach()`
 - ▶ detach the OS thread from the C++ thread object
 - ▶ the OS thread will continue its execution, even when the thread object is destroyed
 - ▶ the thread cannot be joined any more

1.3 C++ Threads ...

Example: Hello world ( 01/helloThread.cpp)

```
#include <iostream>
#include <thread>

void sayHello()
{
    std::cout << "Hello World!\n";
}

int main(int argc, char **argv)
{
    std::thread t(sayHello);
    t.join();
    return 0;
}
```

Parallel Processing

Winter Term 2024/25

Stand: October 23, 2024

1.3 C++ Threads ...

Example: Summation of an array with multiple threads

```
#include <iostream>                                     (☞ 01/sum.cpp)
#include <thread>

#define N 5
#define M 1000

/* This function is called by each thread */
void sumRow(int *row, long *res)
{
    int i;
    long sum = 0;

    for (i=0; i<M; i++)
        sum += row[i];

    *res = sum;    /* return the sum. */
}
```

1.3 C++ Threads ...

```
/* Initialize the array */
void initArray(int array [N] [M])
{
    ...
}

/* Main program */
int main(int argc, char **argv)
{
    int array [N] [M];
    int i;
    std::thread threads [N];
    long res [N];
    long sum = 0;

    initArray(array); /* initialize the array */
```

1.3 C++ Threads ...

```
/* Create a thread for each row and pass the pointer to the row and the
pointer to the result variable as an argument */
for (i=0; i<N; i++) {
    threads[i] = std::thread(sumRow, array[i], &res[i]);
}

/* Wait for the threads' termination and sum the partial results */
for (i=0; i<N; i++) {
    threads[i].join();
    sum += res[i];
}

std::cout << "Sum: " << sum << "\n";
}
```

Compile and link the program

→ g++ -o sum sum.cpp -pthread

1.3 C++ Threads ...

Remarks on the example

- When creating the thread, any number of parameters can be passed to the thread function
- Since the thread function has no return value, we pass the address of a result variable (`&res[i]`) as a parameter
 - the thread function will store its result there
 - caution: since `res` is a local variable, the threads must be joined before the method exits
- No synchronization (other than `join()`) is required
 - each thread stores to a different element of `res`
- With `join()`, we can only wait for a specific thread
 - inefficient, when the threads have different execution times

1.3 C++ Threads ...

Synchronization: mutex variables

- Behavior similar to a binary semaphore
 - states: locked, unlocked; initial state: unlocked
- Declaration (and initialization):

```
std::mutex mutex;
```
- To lock the mutex, create an object of class std::unique_lock:
 - `std::unique_lock<std::mutex> lock(mutex);`
 - the mutex is automatically unlocked when lock is destroyed,
i.e., when execution leaves the current block
- Class mutex does not allow recursive locking
 - i.e., the same thread cannot lock the mutex twice
 - use class recursive_mutex for this purpose

1.3 C++ Threads ...

Synchronization: condition variables

- Declaration (and initialization):

```
std::condition_variable cond;
```

- Important methods:

- `wait: void wait(unique_lock<mutex>& lock)`

- thread is blocked, the mutex wrapped by lock will be unlocked temporarily

- signaling thread keeps the mutex, i.e., the signaled condition may no longer hold when `wait()` returns!

- typical use: `while (!condition_met)`
 `cond.wait(lock);`

- signal just one thread: `void notify_one()`

- signal all threads: `void notify_all()`

1.3 C++ Threads ...

Example: simulating a monitor with C++ threads

```
#include <thread>                                     (☞ 01/monitor.cpp)
#include <mutex>           // Defines std::mutex
#include <condition_variable> // Defines std::condition_variable

std::mutex mutex;
std::condition_variable cond;
volatile int ready = 0;
volatile int result;

void storeResult(int arg) {
    std::unique_lock<std::mutex> lock(mutex);
    result = arg; /* store result */
    ready = 1;
    cond.notify_all();
    // The 'lock' object is destroyed when the method ends, thus unlocking the mutex!
}
```

1.3 C++ Threads ...

```
int readResult()
{
    std::unique_lock<std::mutex> lock(mutex);
    while (ready != 1)
        cond.wait(lock);
    return result; // mutex unlocked automatically when 'lock' is destroyed.
}
```

- while is important, since the waiting thread unlocks the mutex
 - ↳ another thread could destroy the condition again before the waiting thread regains the mutex
(although this cannot happen in this concrete example!)
