# Distributed Systems

Winter Term 2024/25

## 2 Middleware

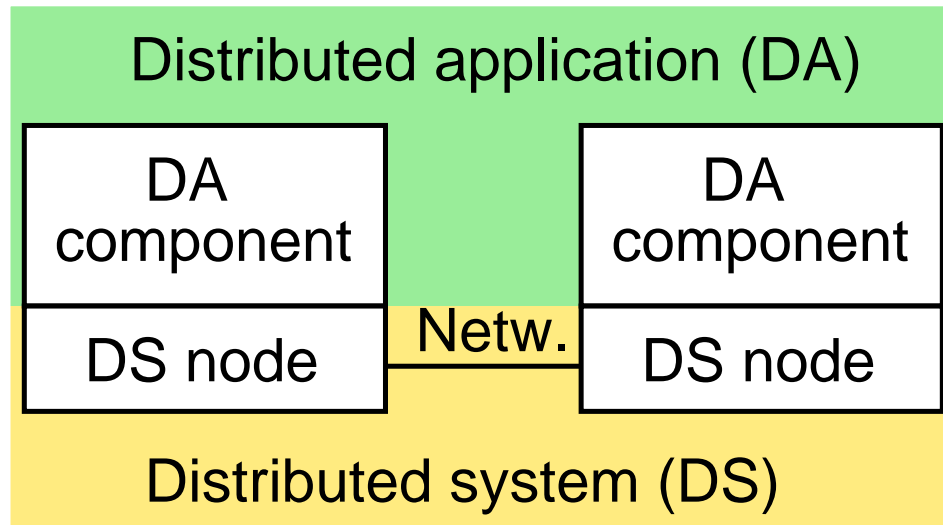

### Content

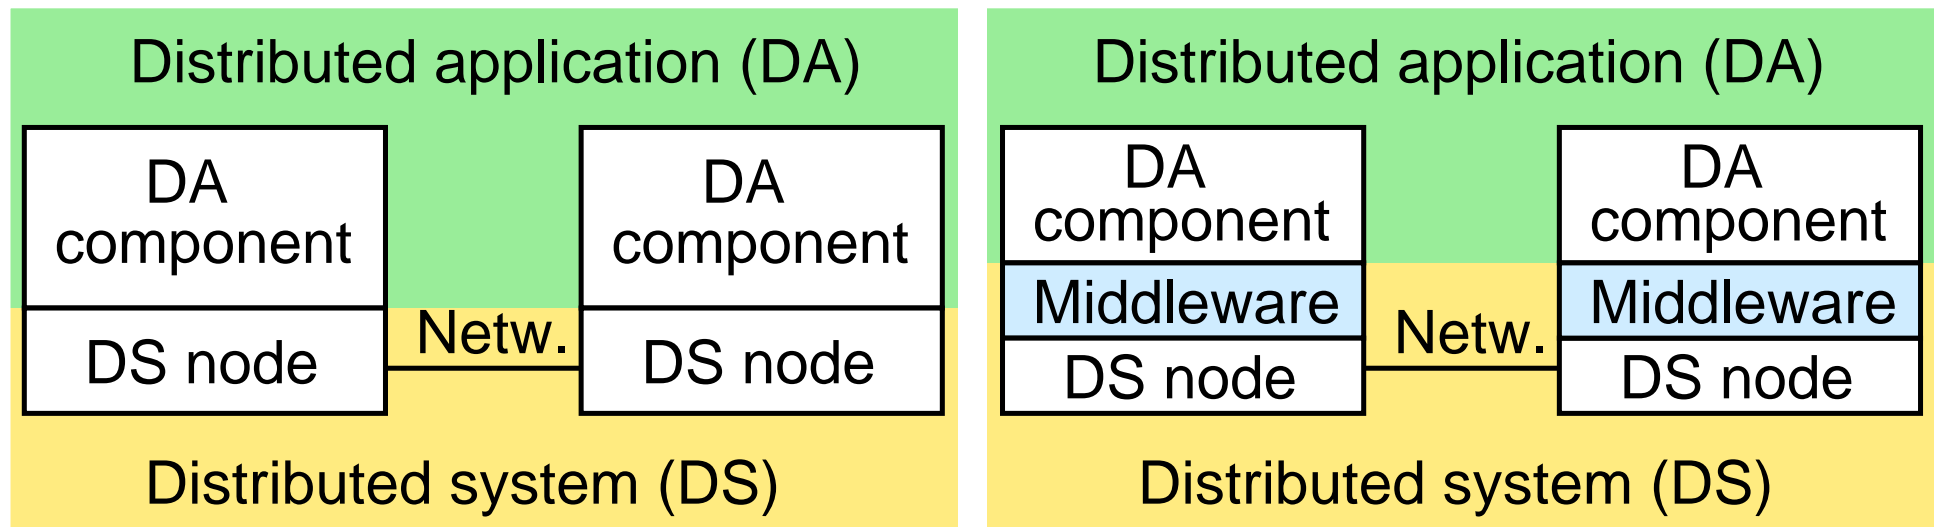

- ➔ Communication in distributed systems
- ➔ Communication-oriented middleware
- ➔ Application-oriented middleware

### Literature

- ➔ Hammerschall: Ch. 2, 6
- ➔ Tanenbaum, van Steen: Ch. 2
- ➔ Colouris, Dollimore, Kindberg: Ch. 4.4

- ➔ DA uses DS for communication between its components
- ➔ DSs generally only offer simple communication services
  - ➔ direct use: **network programming**
- ➔ **Middleware** offers more intelligent interfaces
  - ➔ hides details of network programming

- ➔ DA uses DS for communication between its components
- ➔ DSs generally only offer simple communication services
  - ➔ direct use: **network programming**
- ➔ **Middleware** offers more intelligent interfaces
  - ➔ hides details of network programming

- ➔ Middleware is the interface between distributed application and distributed system
- ➔ Goal: hide distribution aspects from application
  - ➔ transparency (👉 1.3)
- ➔ Middleware can also provide additional services for applications
  - ➔ huge differences in existing middleware
- ➔ Distinction:
  - ➔ **communication-oriented middleware** (👉 2.2)
    - ➔ (only) abstraction from network programming
  - ➔ **application-oriented middleware** (👉 2.3)
    - ➔ besides communication, the focus is on support of distributed applications

### 2.1 Communication in Distributed Systems

- ➔ Basis: **interprocess communication (IPC)**
  - ➔ exchange of messages between processes (☞ **BS\_I: 3.2**)
    - ➔ on the same or on different nodes
    - ➔ e.g. via ports, mailboxes, streams, ...
- ➔ For distribution: network protocols (☞ **RN\_I**)
  - ➔ relevant topics etc: addressing, reliability, guaranteed ordering, timeouts, acknowledgements, marshalling
- ➔ Interface for network programming: sockets (☞ **RN\_II**)
  - ➔ datagrams (UDP) and streams (TCP)

### Synchronous Communication

- ➔ Sender and receiver block when calling a send or receive operation
  - ➔ receiver is waiting for a request
  - ➔ sender is waiting for the reply
- ➔ Tight coupling between sender and receivers
  - ➔ advantage: easy to understand model
  - ➔ disadvantage: strong dependency, especially in case of error
- ➔ Prerequisites:
  - ➔ reliable and fast network connection
  - ➔ receiver process is available

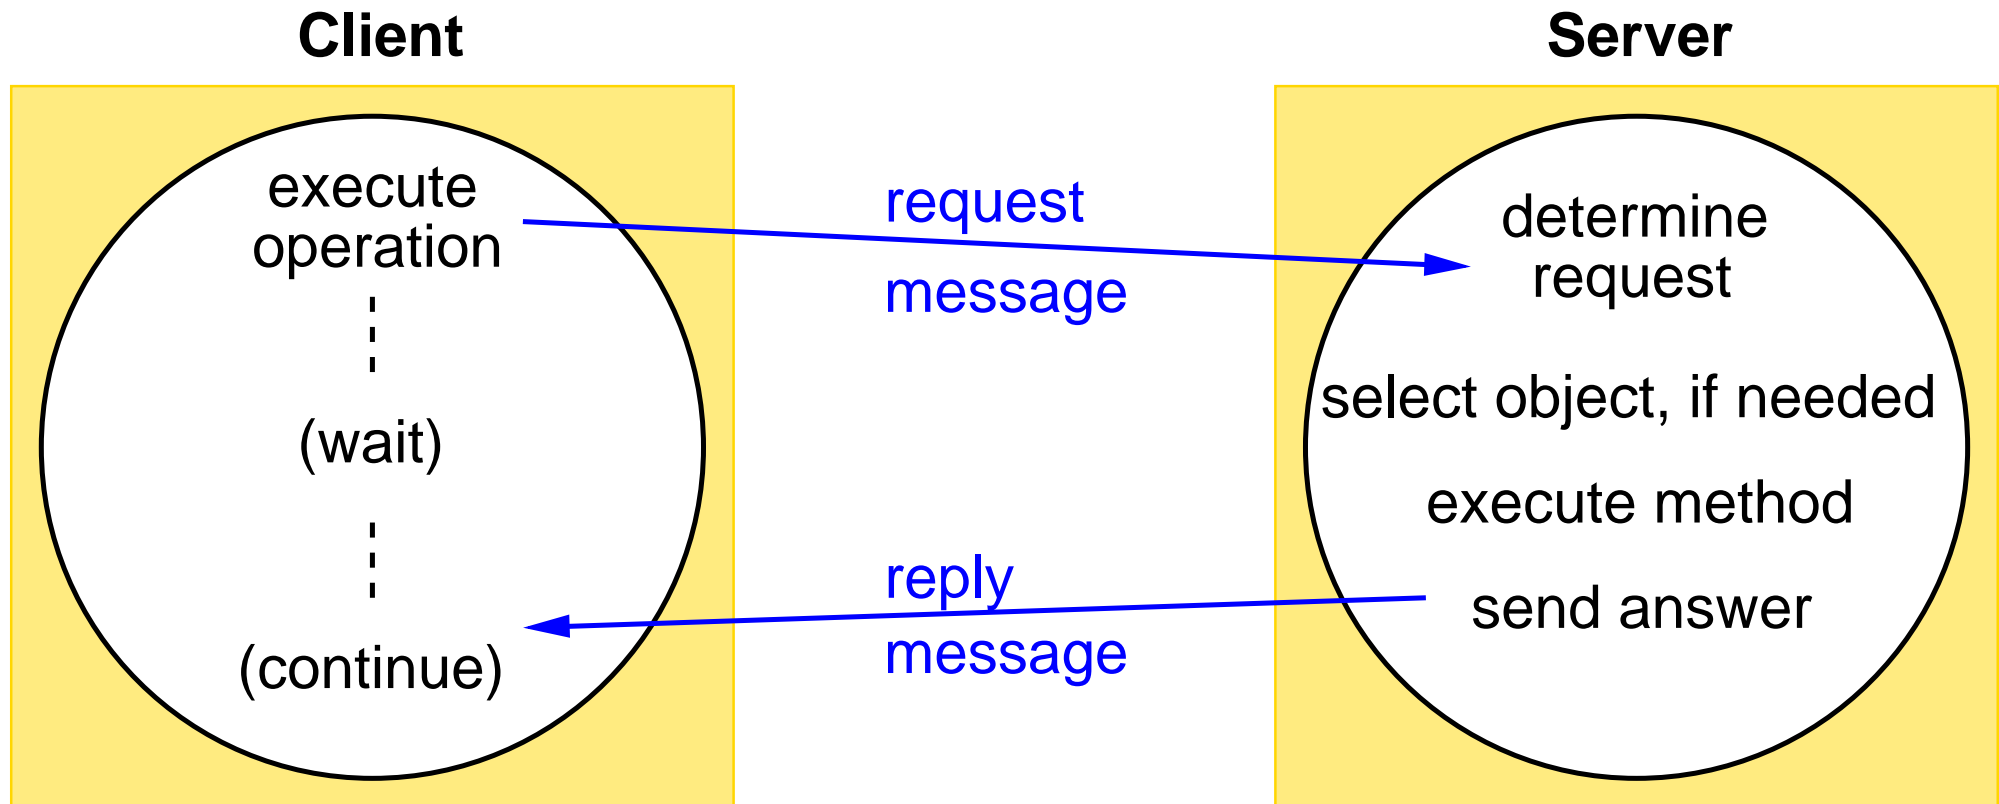

### Asynchronous Communication

- ➔ Sender is not blocked, can continue immediately after sending the message
- ➔ Incoming messages are buffered at the receiver
- ➔ Answers are optional
  - ➔ receiver can reply asynchronously to the sender
- ➔ More complex implementation and use as with synchronous communication, but usually more efficient
- ➔ Only loose coupling between the processes
  - ➔ receiver does not have to be ready for reception
  - ➔ less dependent in case of errors

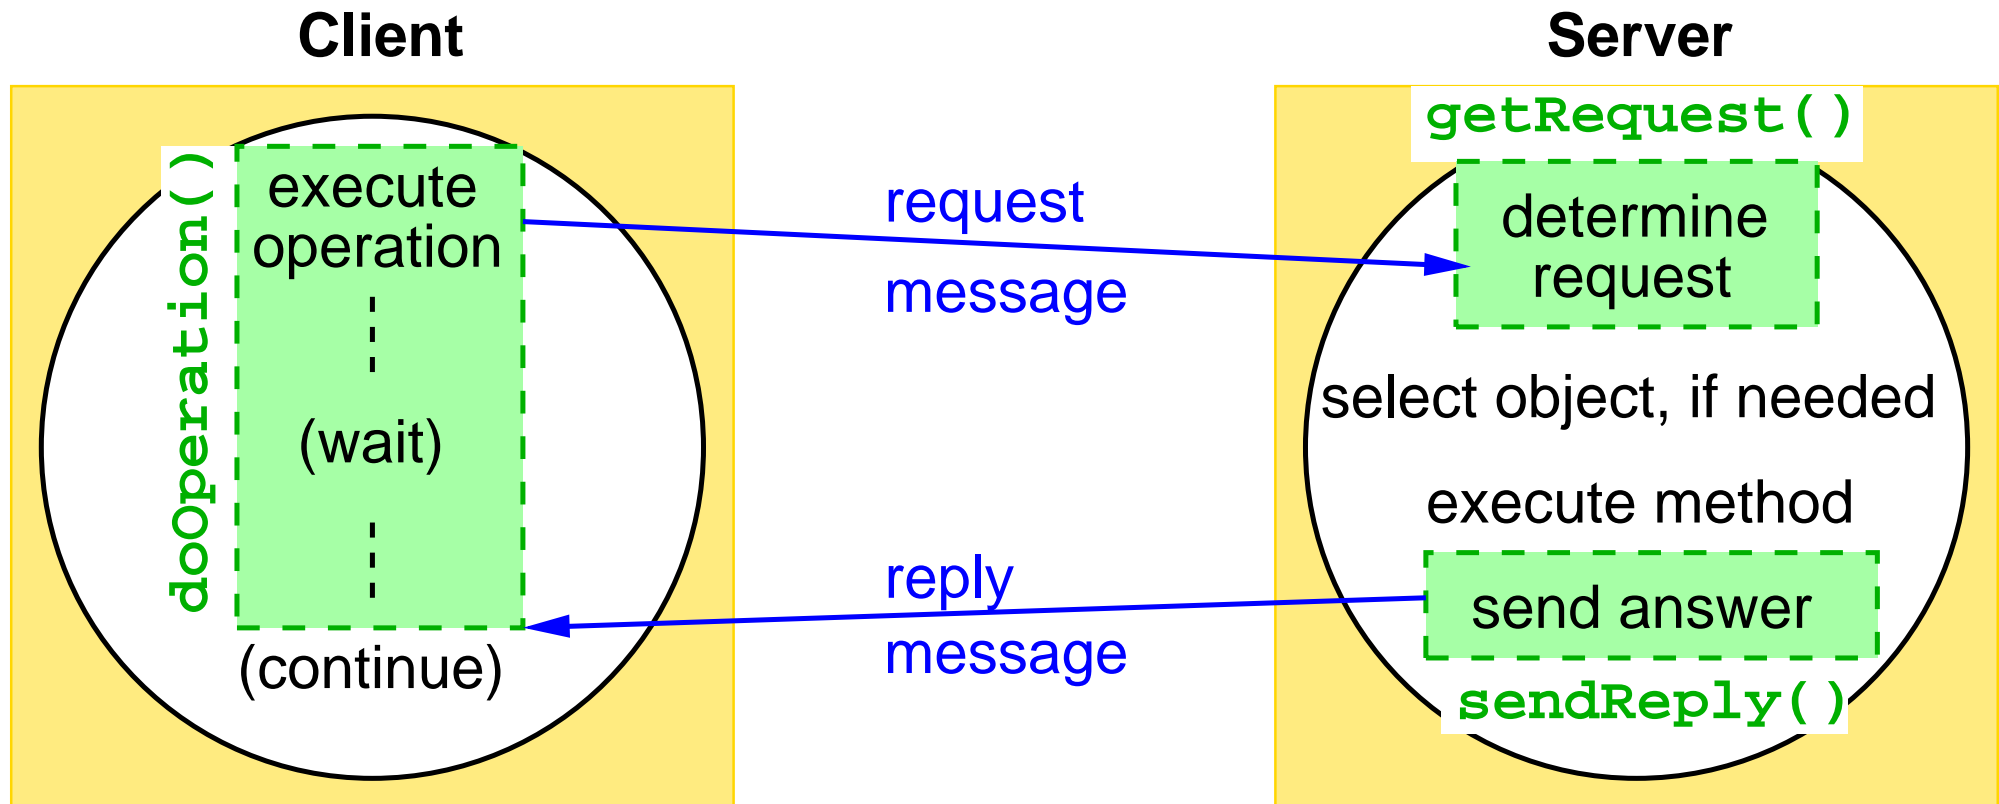

### Client/Server Communication

- ➡ Mostly synchronous: client blocked until response arrives
- ➡ Variants: asynchronous (non blocking), one way (without answer)

### Client/Server Communication

- ➔ Mostly synchronous: client blocked until response arrives
- ➔ Variants: asynchronous (non blocking), one way (without answer)

### Client/Server Communication: Request/Response Protocol

#### ➔ Typical operations:

- ➔ `doOperation()` – send request and wait for result
- ➔ `getRequest()` – wait for request
- ➔ `sendReply()` – send result

#### ➔ Typical message structure:

messageType
requestID
objectReference
methodID
arguments

request / reply ?

unique ID of request (usually int)

reference to remote object (if needed)

method to be called (int / String)

arguments (usually as Byte array)

- ➔ request ID + sender ID result in unique message ID
  - ➔ e.g. to map an answer to its query

# Distributed Systems

Winter Term 2024/25

24.10.2024

### Client/Server Communication: Error Handling

- ➔ Request and/or response messages may be lost
- ➔ Client sets a timeout when sending a request
  - ➔ after expiration, request is usually sent again
  - ➔ after a few repetitions: termination with exception
- ➔ Server discards duplicate requests if request has already been / is still being processed
- ➔ For lost response messages:
  - ➔ idempotent operations can be executed again
  - ➔ otherwise: save results of operations in a history
    - ➔ for repeated request: only resend the result
    - ➔ delete history entries when next request arrives; if necessary confirmations for results can also be used

## 2.2 Communication-oriented Middleware

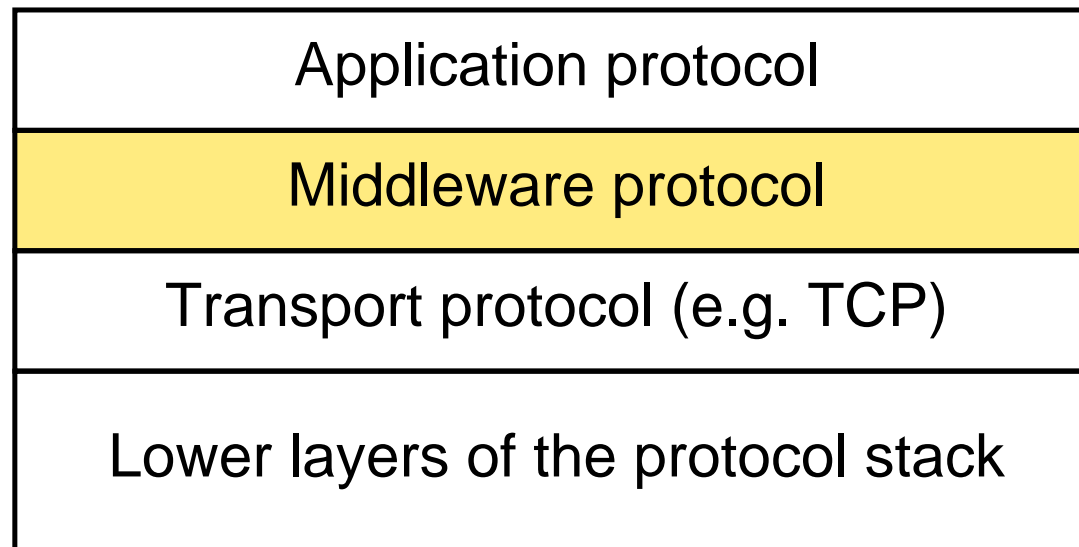

- ➔ Focus: provision of a communication infrastructure for distributed applications
- ➔ Tasks:
  - ➔ communication
  - ➔ dealing with heterogeneity
  - ➔ error handling

### Communication

- ➔ Provision of a middleware protocol
- ➔ Localization and identification of communication partners
- ➔ Integration with process and thread management

### Heterogeneity

- ➔ Problem with data transmission:
  - ➔ heterogeneity in distributed systems
- ➔ Heterogeneous hardware and operating systems
  - ➔ different byte order
    - ➔ little endian vs. big endian
  - ➔ different character encoding
    - ➔ e.g.. ASCII / Unicode / UTF-8 / UTF-16
- ➔ Heterogeneous programming languages
  - ➔ different representation of simple and complex data types in the main memory

### Heterogeneity: Solutions (☞ RN\_I)

- ☞ Use of generic, standardized data formats
  - ☞ known to all communication partners and middleware
  - ☞ platform-specific formats for middleware (e.g. CDR for CORBA) or external formats, e.g. XML
- ☞ Heterogeneity of hardware and operating system
  - ☞ is handled transparently for the applications by the middleware
- ☞ Heterogeneity of programming languages
  - ☞ applications need to convert data to higher-level format and back (**marshaling** / **unmarshaling**)
    - ☞ necessary code is usually generated automatically
      - ☞ client stub / server skeleton

### Error Handling

- ➔ Possible errors due to distribution
  - ➔ incorrect transmission (incl. loss of messages)
    - ➔ handled by the protocols of the distributed system:
      - ➔ checksums, CRC
      - ➔ retransmission of packets (e.g. TCP)
  - ➔ failure of components (network, hardware, software)
    - ➔ handled by middleware or application:
      - ➔ acceptance of the error
      - ➔ retransmission of messages
      - ➔ replication of components (error avoidance)
      - ➔ controlled termination of the application

### 2.2.2 Programming Models

- ➔ Programming model defines two concepts:
  - ➔ communication model
    - ➔ synchronous vs. asynchronous
  - ➔ programming paradigm
    - ➔ object-oriented vs. procedural
- ➔ Three common programming models for middleware:
  - ➔ message-oriented model (asynchronous / arbitrary)
  - ➔ remote procedure call (synchronous / procedural)
  - ➔ remote method invocation (synchronous / object-oriented)

### Message-Oriented Model

- ➔ Sender puts message in receiver's queue

- ➔ Receiver accepts message as soon as he is ready
- ➔ Extensive decoupling of transmitter and receiver
- ➔ No method or procedure calls
  - ➔ data is packed and sent by the application
  - ➔ no automatic reply message

### Remote Procedure Call (RPC)

- ➔ Allows a client to call a procedure in a remote server process

- ➔ Communication according to request / response principle

### Remote Method Invocation (RMI)

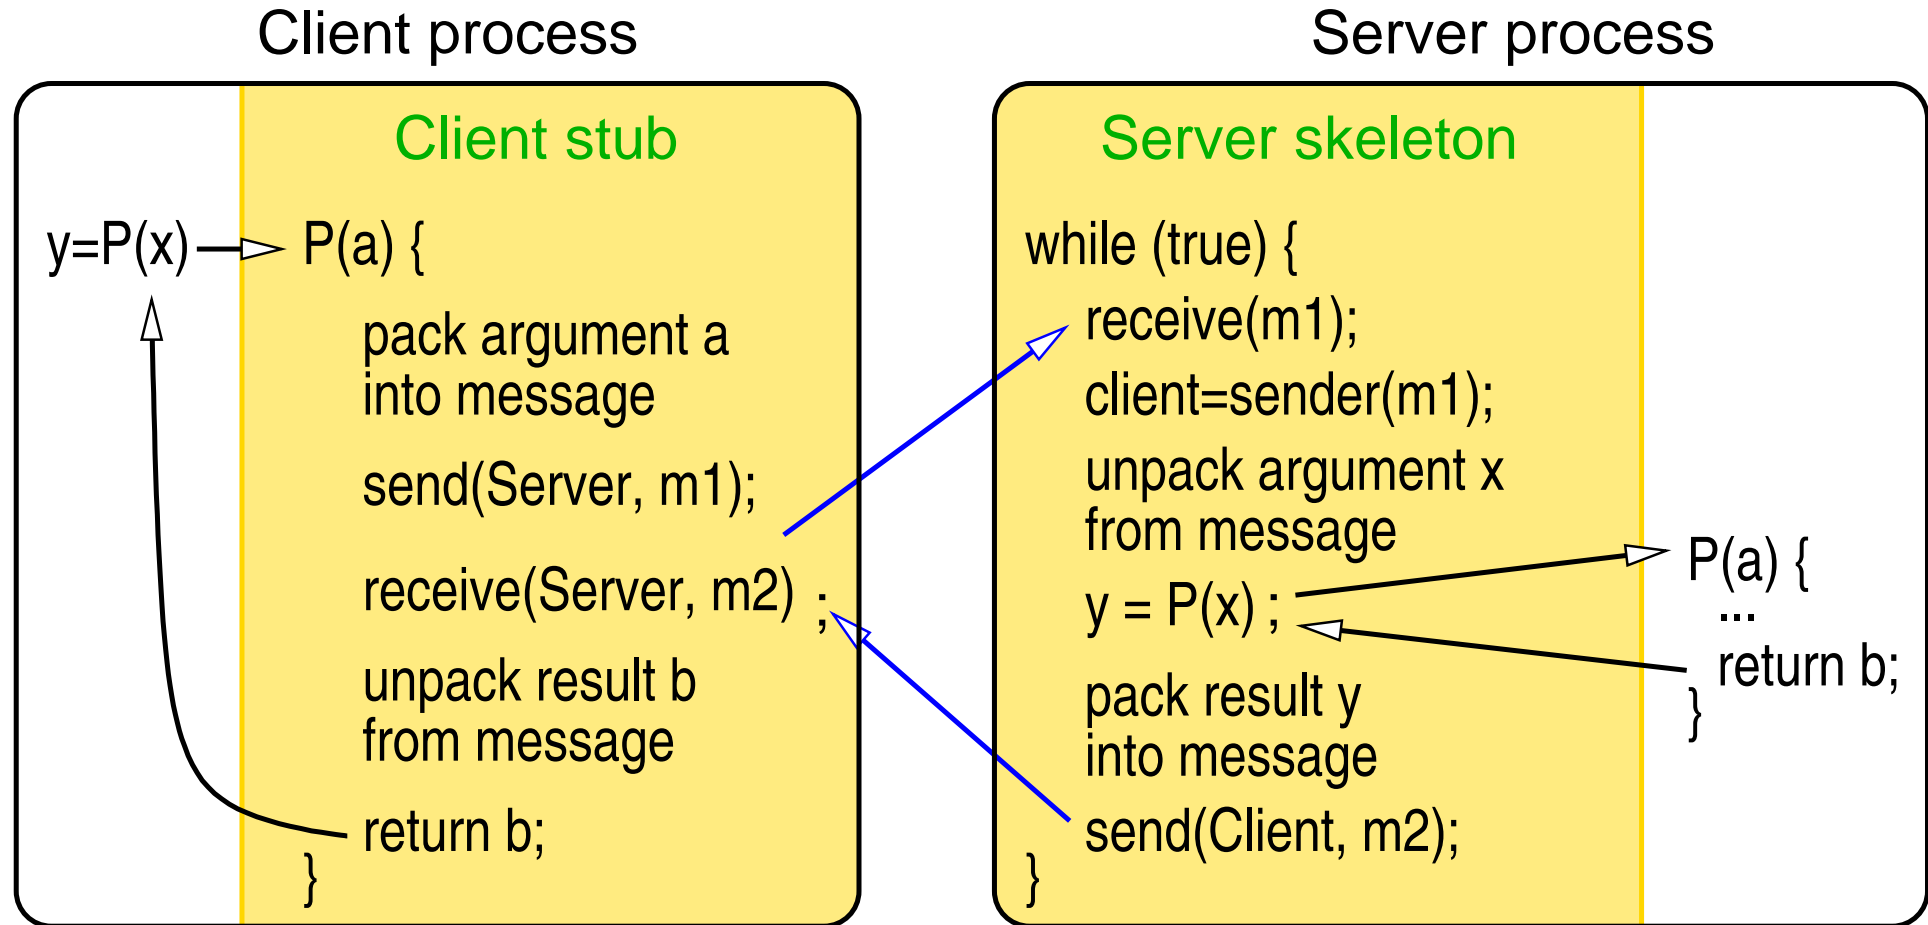

- ➔ Allows an object to call methods of a remote object
- ➔ In principle very similar to RPC

### Common Basic Concepts of Remote Calls

- ➔ Client and server are decoupled by interface definition
  - ➔ defines names of calls, parameters and return values
- ➔ Introduction of **client stubs** and **server skeletons** as an access interface
  - ➔ are automatically generated from interface definition
    - ➔ IDL compiler (IDL = interface definition language)
  - ➔ are responsible for marshaling / unmarshaling as well as for the actual communication
  - ➔ realize access and location transparency

### How Client Stub and Server Skeleton Work (RPC)

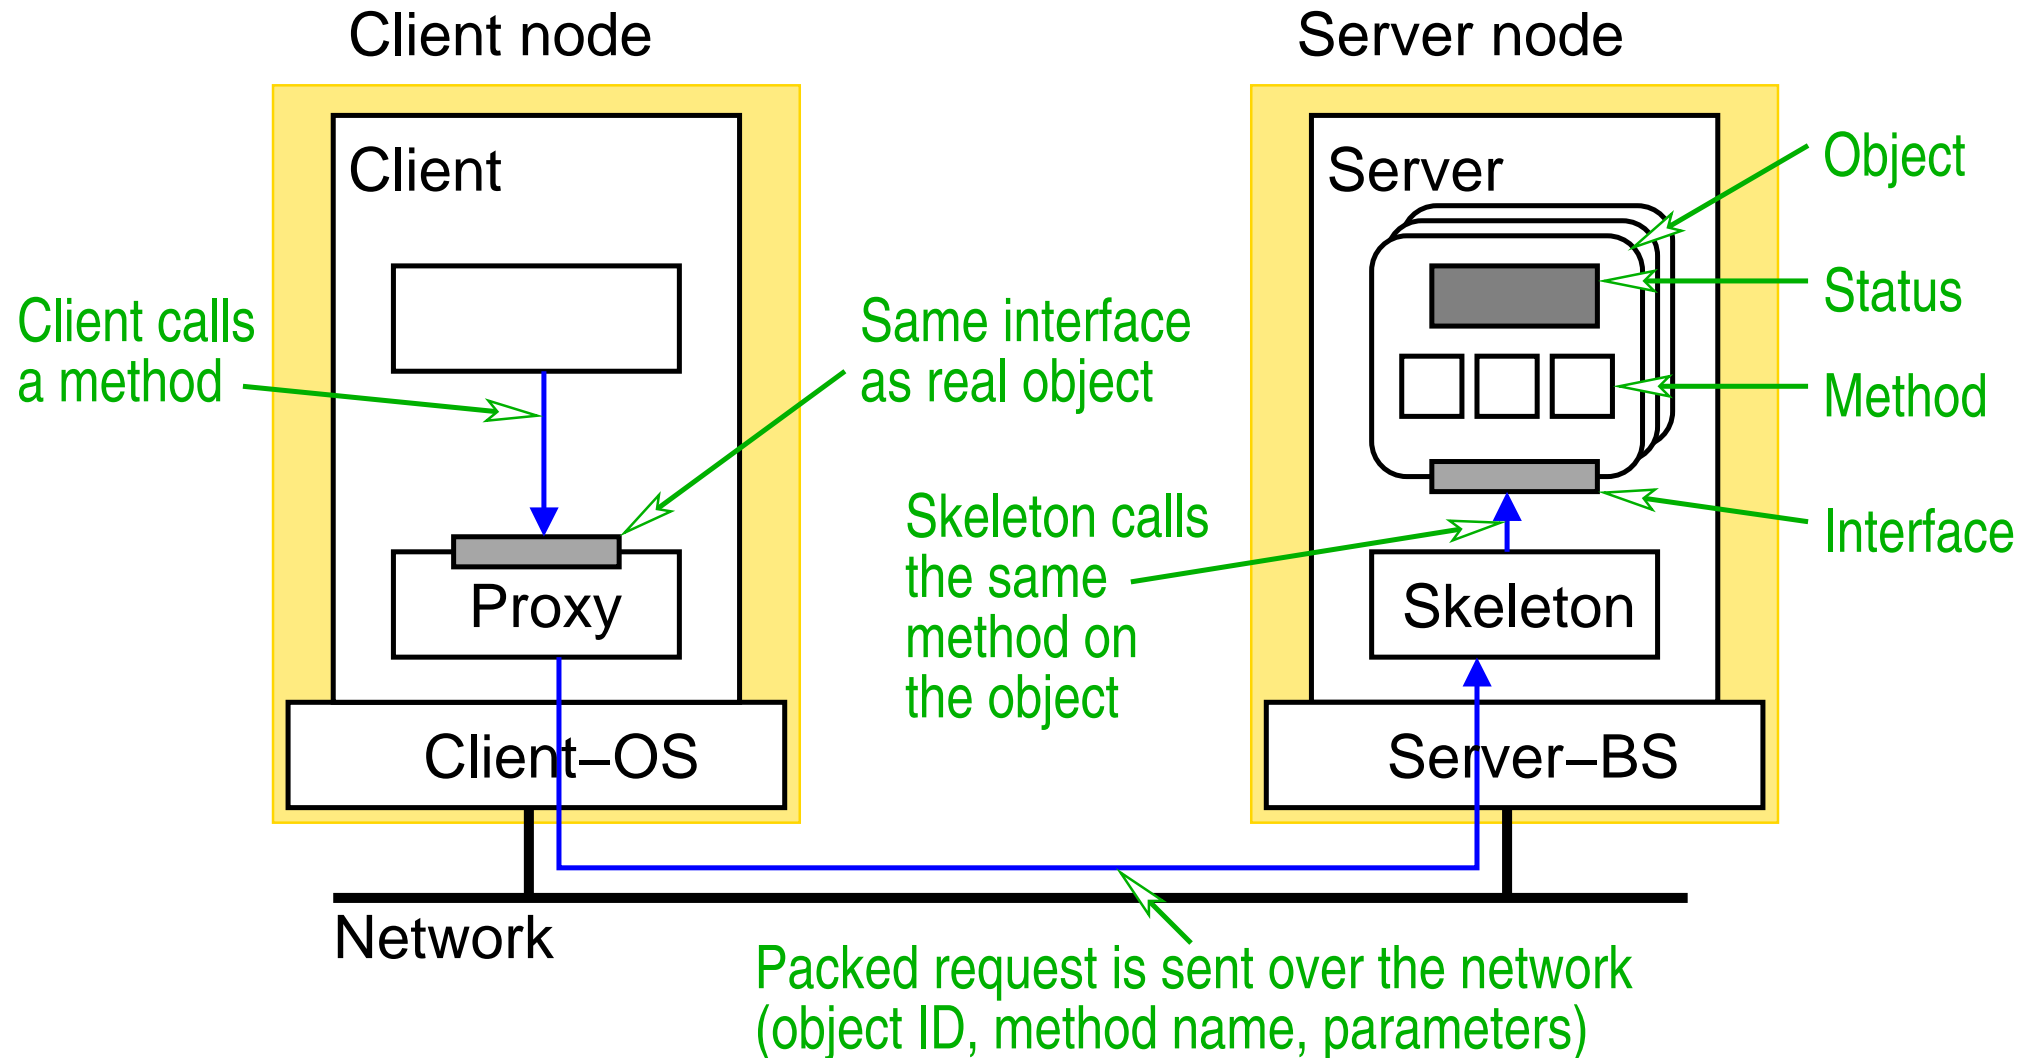

### Basis of RMI: The Proxy Pattern

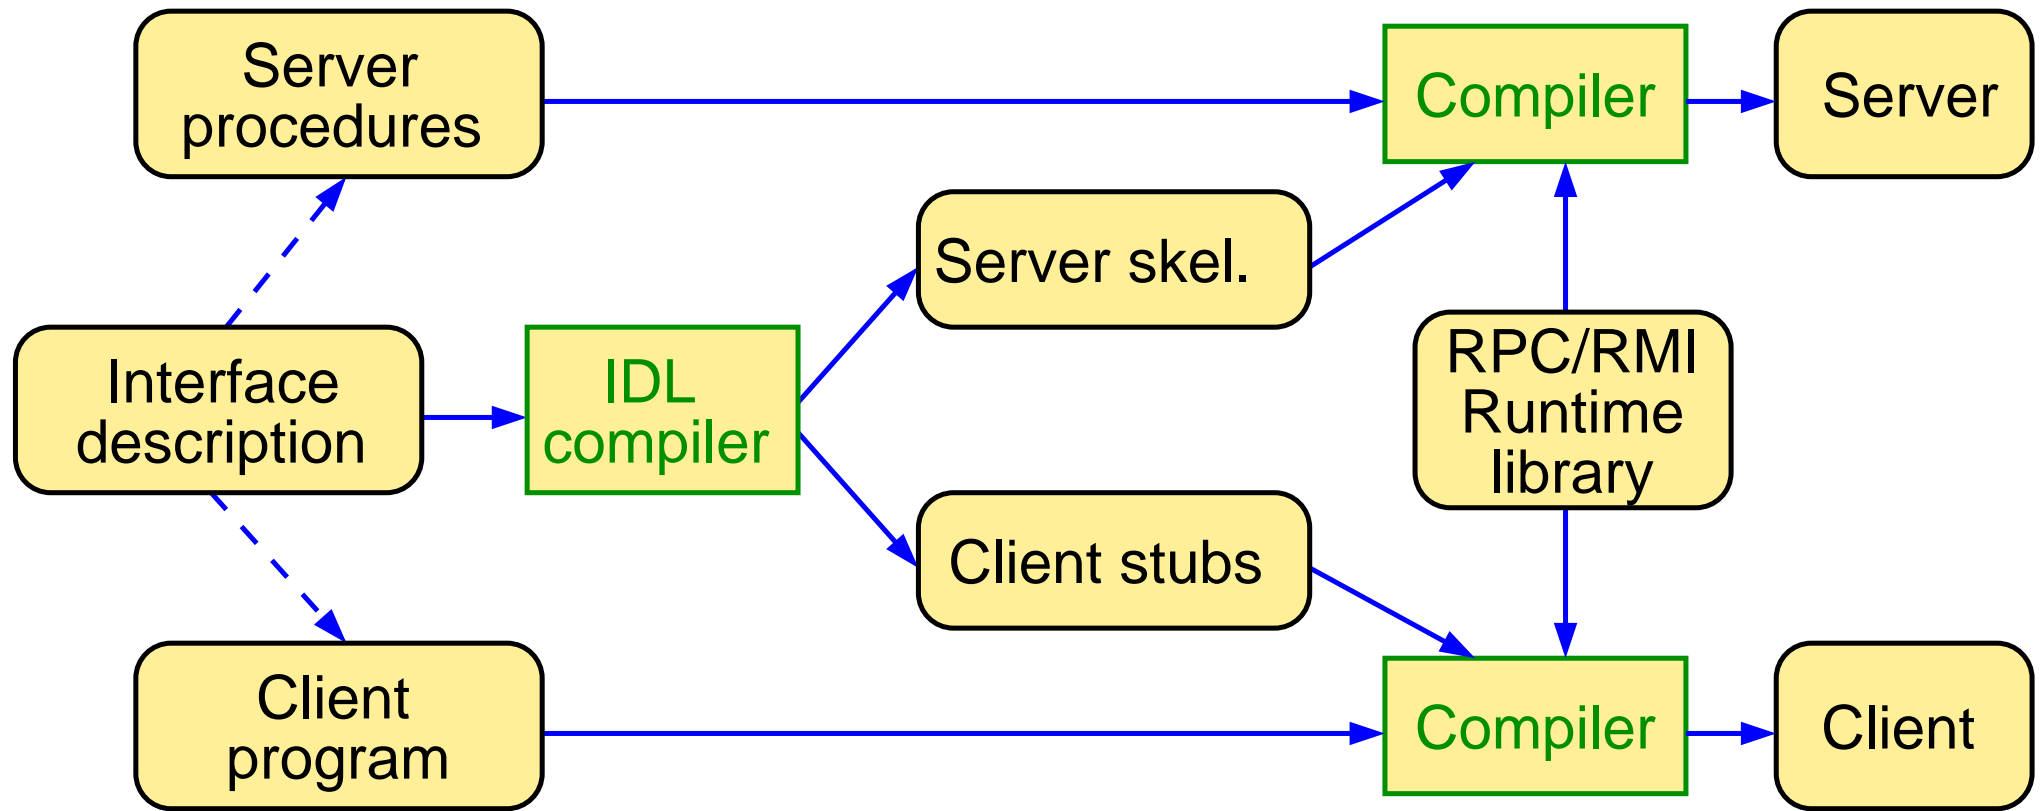

- ➔ Client works with a deputy object (**proxy**) of the actual server object
- ➔ proxy and server object implement the same interface
- ➔ client only knows / uses this interface

### Flow of a Remote Method Call

### Creation of a Client/Server Program

➡ Applies in principle to all realizations of remote calls

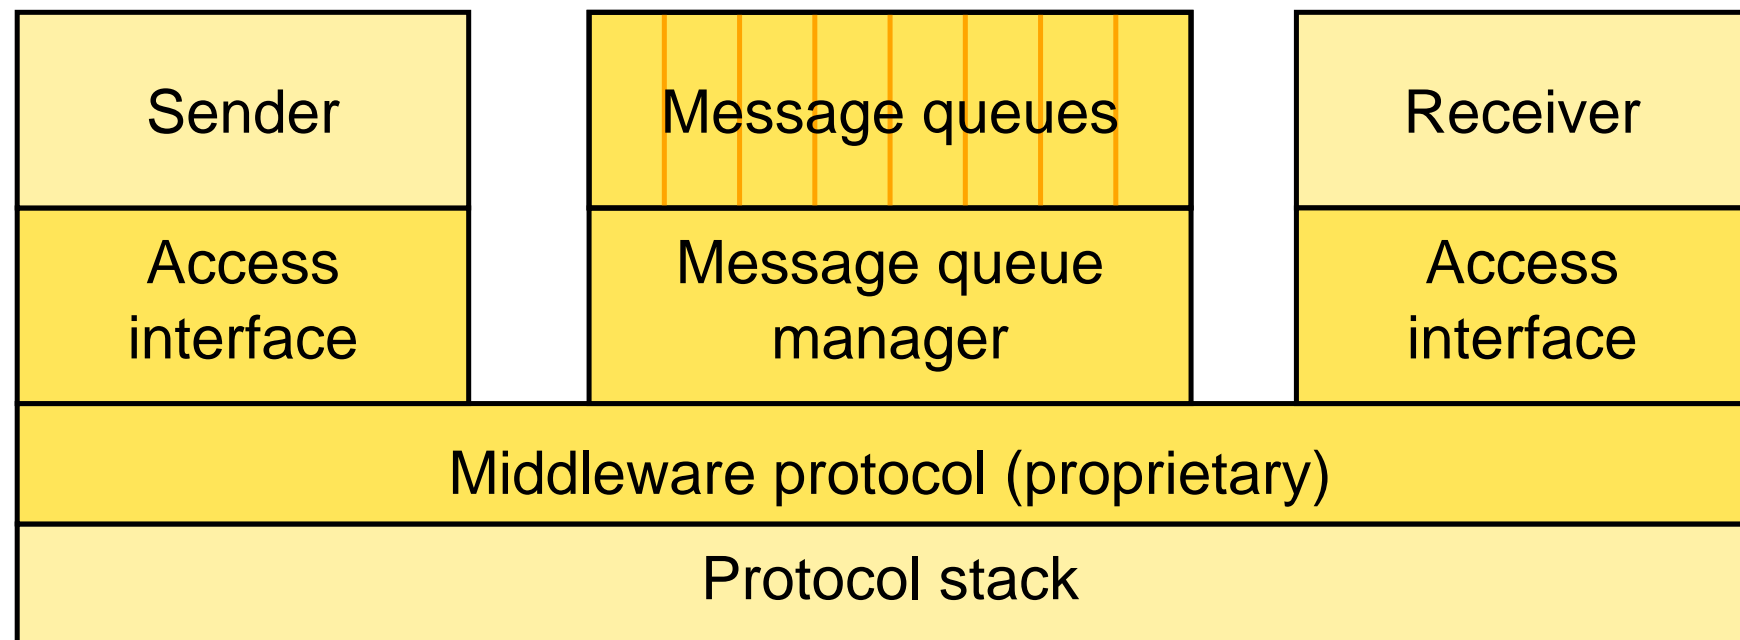

### 2.2.3 Middleware Technologies

- ➔ Realize (at least) one of the programming models
  - ➔ rely on open standards / standardized interfaces
- ➔ Remote procedure call
  - ➔ SUN RPC, DCE RPC, Web Services, ...
- ➔ Remote method invocation
  - ➔ Java RMI (👉 **3**), CORBA, ...
- ➔ Message-oriented middleware technologies
  - ➔ MOM: message oriented middleware, messaging systems
  - ➔ mainly for EAI
  - ➔ Java Message Service, WebSphereMQ (MQSeries), ...

### 2.2.4 Message Oriented Middleware (MOM)

- ➔ Middleware technology for the message-oriented model
- ➔ In addition to message exchange also other services, especially queue management

### Message Queue Infrastructure

- ➔ Access to queues is only possible locally
  - ➔ local: same computer or same subnet
- ➔ Transport of messages across subnet boundaries by queue administrators (routers)

### Variants of message exchange

- ➔ Point-to-point communication
  - ➔ communication between two defined processes
  - ➔ simplest model: asynchronous communication
  - ➔ enhancement: request/reply model
    - ➔ enables synchronous communication via asynchronous middleware
- ➔ Broadcast communication
  - ➔ Message is sent to all reachable receivers
  - ➔ one implementation: publish/subscribe model
    - ➔ publishers publish messages/news on a topic
    - ➔ subscribers subscriber to certain topics
    - ➔ mediation via a broker

### Example: Java Message Service

- ➔ Part of the Java Enterprise Edition (Java EE)
- ➔ Unified Java interface for MOM services
- ➔ Distinguishes two roles:
  - ➔ JMS provider: the respective MOM server
  - ➔ JMS client: sender or receiver of messages
- ➔ JMS supports:
  - ➔ asynchronous point-to-point communication
  - ➔ request/reply model
  - ➔ publish/subscribe model
- ➔ JMS defines corresponding access objects and methods

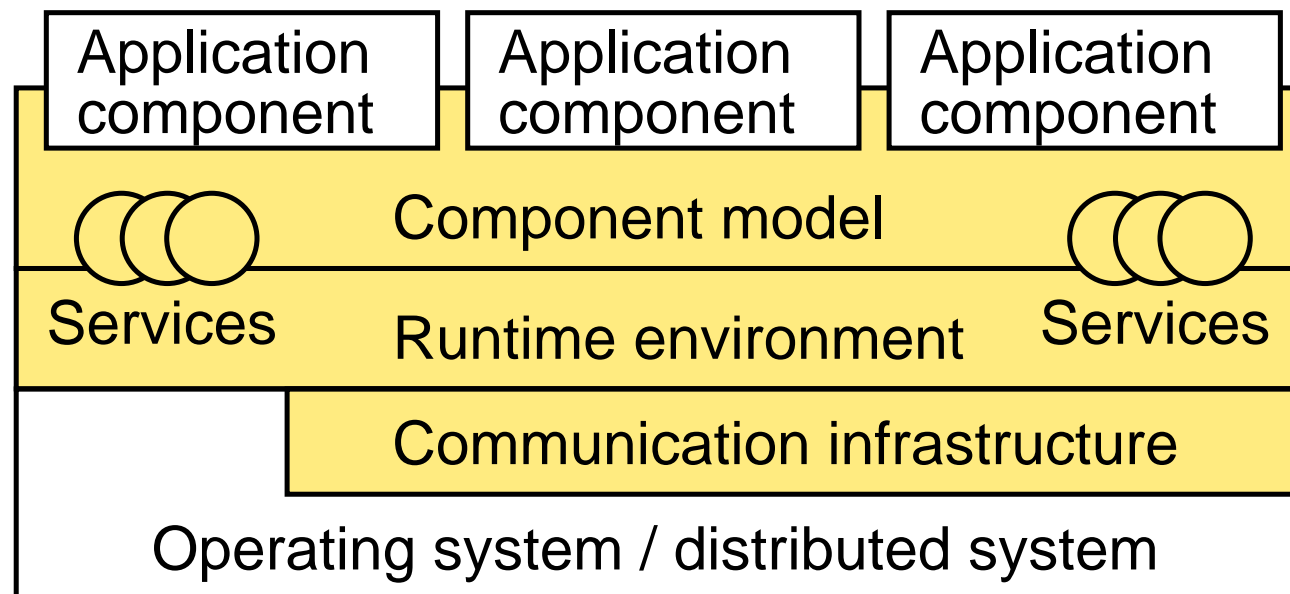

### 2.2.5 Summary

- ➔ Tasks: Communication, dealing with heterogeneity, error handling
- ➔ Programming models:
  - ➔ message-oriented model (asynchronous)
    - ➔ basis: message queues
    - ➔ refinements:
      - ➔ request/reply model (synchronous)
      - ➔ publish/subscribe model (broadcast)
  - ➔ remote procedure or method calls
    - ➔ synchronous: request and response
    - ➔ generated stubs for (un-)marshaling

## 2.3 Application-oriented Middleware

- ➔ Based on communication-oriented middleware
- ➔ Extends it by:
  - ➔ runtime environment
  - ➔ services
  - ➔ component model

- ➔ Based on node operating systems of the distributed system
  - ➔ Operating system (OS) manages processes, memory, I/O, ...
  - ➔ provides basic functionality
    - ➔ starting / stopping processes, scheduling, ...
    - ➔ interprocess communication, synchronization, ...
- ➔ Runtime environment extends functionality of the OS:
  - ➔ improved resource management
    - ➔ e.g. concurrency, connection management
  - ➔ improved availability
  - ➔ improved security mechanisms

### Resource management

- ➔ Middleware goes beyond simple OS functionality
  - ➔ e.g. independently managed main memory areas with individual security criteria
  - ➔ pooling of processes, threads, connections
    - ➔ are created for stock and made available as required
  - ➔ possible, since middleware is specific to certain classes of applications
- ➔ Goal: improved performance, scalability and availability

### Concurrency

- ➔ Concurrency in this context:
  - ➔ isolated parallel processing of requests
- ➔ Concurrency can be implemented via processes or threads
  - ➔ threads (lightweight processes): concurrent activities within processes
    - ➔ threads in the same process share all resources
  - ➔ advantages and disadvantages:
    - ➔ processes: high resource requirements, not well scalable, good protection, with low concurrency
    - ➔ threads: well scalable, no mutual protection, with high concurrency

### Concurrency ...

- ➔ Middleware takes over automatic generation / administration of threads in the case of concurrent orders, e.g.
  - ➔ *single-threaded*
    - ➔ only one thread, sequential processing
  - ➔ *thread-per-request*
    - ➔ a new thread is created for each request
  - ➔ *thread-per-session*
    - ➔ a new thread is created for each session (client)
  - ➔ *thread pool*
    - ➔ fixed number of threads, incoming requests are distributed automatically
      - ➔ saves thread generation costs
      - ➔ limits resource consumption

### Connection management

- ➔ Connection here means: endpoints of communication channels
  - ➔ occur at tier boundaries (between process spaces)
    - ➔ e.g. client/server interface, database access
  - ➔ are assigned to a process/thread, if in the active state
  - ➔ require resources (memory, processor time)
  - ➔ opening and closing connections is costly
- ➔ To save resources: pooling of connections
  - ➔ connections are initialized to stock and placed in pool
  - ➔ each thread/process receives a connection on demand
  - ➔ after use: return connection to pool

### Availability

- ➔ Requirement to the application,  
but mainly implemented by the runtime environment
- ➔ Downtimes are caused by
  - ➔ failure of a hardware or software component
  - ➔ overload of a hardware or software component
  - ➔ maintenance of a hardware or software component
- ➔ Frequent technology for ensuring availability: cluster
  - ➔ replication of hardware and software
  - ➔ cluster appears externally as one unit
  - ➔ two types: fail-over cluster / load-balancing cluster

### Security

- ➔ Distributed applications are vulnerable due to their distribution
- ➔ Middleware supports different security models
- ➔ Security requirements:
  - ➔ **authentication:**
    - ➔ proves the identity of the user / a component
    - ➔ e.g. by password query (for users) or cryptographic techniques and certificates (for components)
  - ➔ **authorization:**
    - ➔ definition of access rights for users to specific services
      - ➔ or more fine grained: methods and attributes
    - ➔ requires secure authentication

### Security ...

#### ➔ Security requirements ...:

##### ➔ **confidentiality**

- ➔ information cannot be intercepted during transmission in the network
- ➔ technique: encryption

##### ➔ **integrity**

- ➔ transmitted data cannot be changed without being noticed
- ➔ techniques: cryptographic checksum (message digest, fingerprint), digital signature
  - ➔ digital signature also ensures authenticity of the sender

### Security ...

- ➔ Security mechanisms:
  - ➔ encryption
    - ➔ symmetric (e.g. AES, IDEA)
      - ➔ same key for encryption and decryption
    - ➔ asymmetric (public key algorithms, e.g. RSA)
      - ➔ public key for encryption
      - ➔ private key for decrypting
  - ➔ digital signature
    - ➔ ensures integrity of a message and authenticity of the sender as well as nonrepudiation
  - ➔ certificate
    - ➔ certifies that public key and person (or component) belong together

### Name service (directory service) (👉 4)

- ➡ Publication of available services
  - ➡ in the intranet or Internet
- ➡ Assignment of names to references (addresses)
  - ➡ name serves as a unique / unchangeable identifier
  - ➡ the client can request the address of a service via its name
    - ➡ address can change e.g. at restart
  - ➡ goal: decoupling of client and server
- ➡ Examples: JNDI, RMI registry, CORBA interoperable naming service, UDDI registry, LDAP server, Active Directory, ...

### Session management

- ➔ In interactive systems: each instance of a client is assigned its own **session**
  - ➔ deleted when logging out or closing the client
- ➔ Session stores all relevant data (in main memory)
  - ➔ e.g. identification of the user, browser type, "shopping cart", ...
  - ➔ data stored in the server or in the client
  - ➔ transient data: deleted at the end of the session
  - ➔ persistent data: is written to a data carrier (database) at the end of the session.
- ➔ Middleware implements/supports the assignment of requests to sessions (often transparent)
  - ➔ e.g. cookies, HTTP-sessions, session beans, ...

### Transaction management (👉 7.4)

- ➡ Service for interactive, data-centric applications
  - ➡ consistency / integrity of data is important
  - ➡ this means that the entire (maybe distributed) dataset must represent a valid state in itself
- ➡ Typical sequence in applications:
  1. client requests data
  2. client changes the data
  3. client requests that the data be rewritten
  - ➡ problem: steps 1-3 could be performed by two clients at the same time
- ➡ Transaction management allows execution of a sequence of actions as an atomic unit

# Distributed Systems

Winter Term 2024/25

31.10.2024

Roland Wismüller  
Universität Siegen  
roland.wismueller@uni-siegen.de

Stand: October 24, 2024

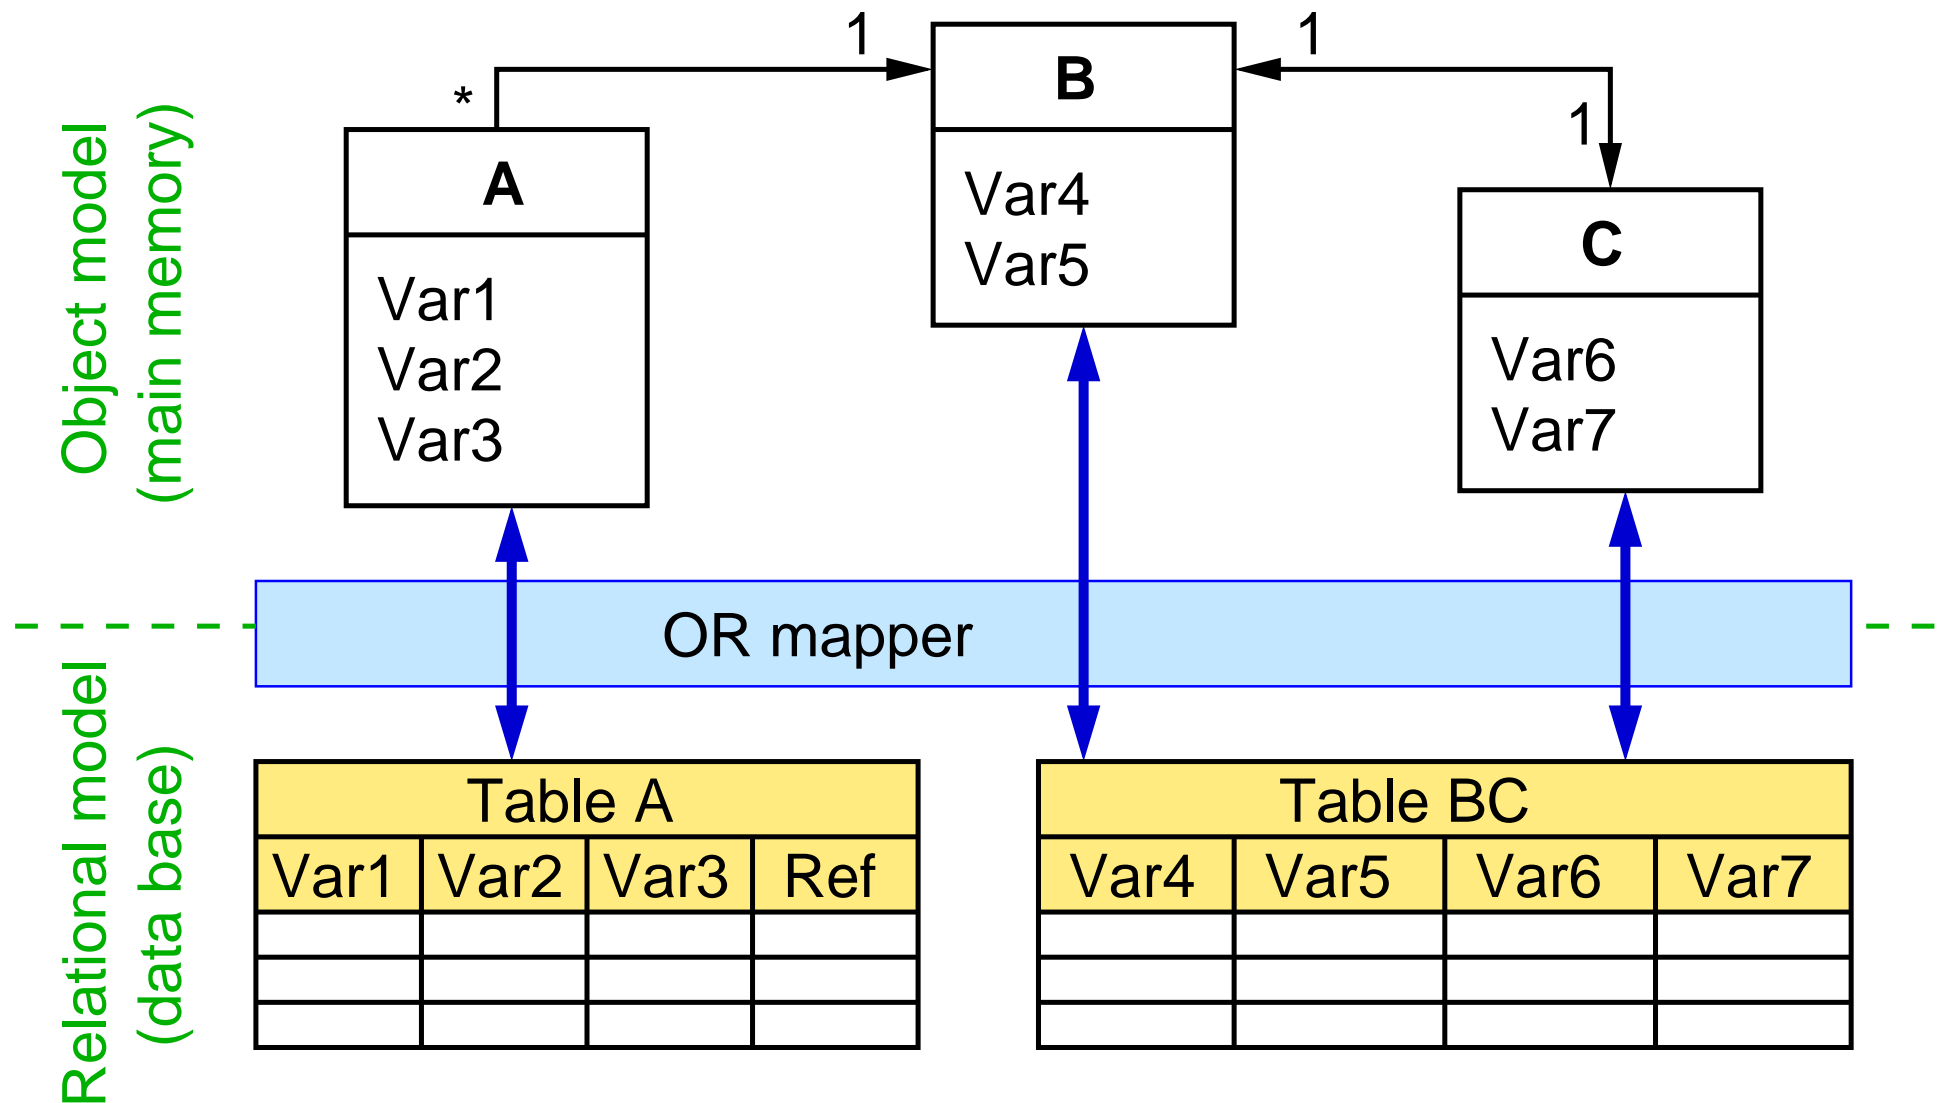

### Persistence service

- ➔ Persistence: all measures for the permanent storage of main memory data
- ➔ Persistence service: intelligent interface to the database
  - ➔ integrated in middleware or as an independent component
  - ➔ most important service for data-centered applications besides transaction management
- ➔ Most common type: object-relational mapper (OR-Mapper)
  - ➔ maps objects in memory to tables in a relational database
    - ➔ class → table
    - ➔ attribute → column
    - ➔ object → row
  - ➔ mapping rules are controlled by application developer

### Persistence service ...

- ➔ Components: “large” objects for structuring applications
- ➔ A component model defines:
  - ➔ the term “component”
    - ➔ structure and properties of the components
    - ➔ mandatory and optional interfaces
  - ➔ interface contracts
    - ➔ how do components interact with each other and with the runtime environment?
  - ➔ component runtime environment
    - ➔ management of the life cycle of components
    - ➔ implicit provision of services: component only specifies its requirements (e.g. persistence)

- ➔ Object request broker (ORB)
  - ➔ distributed objects, remote method calls
  - ➔ variety of services, only basic runtime environment
  - ➔ example: CORBA
- ➔ Application server
  - ➔ focus: support of application logic (middle tier)
  - ➔ services, runtime environment, and component model
  - ➔ today only as part of a middleware platform
- ➔ Middleware platforms
  - ➔ extension of application servers: support of all tiers
    - ➔ distributed applications as well as EAI
  - ➔ examples: Java EE/EJB, .NET/COM, CORBA 3.0/CCM

### Application-oriented middleware

- ➔ Runtime environment
  - ➔ resource management, availability, security
- ➔ Services
  - ➔ name service, session management, transaction management, persistence service
- ➔ Component model
  - ➔ definition of components, interface contracts, runtime environment
